

:host vs :host-context in Angular

`:host` targets the host element of the component itself.

`:host-context()` targets styles based on any ancestor element in the DOM tree.

- Use `:host` to apply component-wide wrappers (e.g., borders, padding).
- Use `:host-context(.dark-theme)` to conditionally style based on parent class.

Both are transformed by Angular's compiler with scope-aware attributes like `[_ngghost-xyz]` or `[_ngcontent-xyz]`.

:host vs :host-context
